

THE IPO

for Alzheimer's.

NOT A STOCK OFFERING.

A public offering of method:
dynamic EEG relationships,
higher-order structure, human
context, uncertainty, and a record
people can question.

A PUBLIC RESEARCH MANDATE

Make the invisible course of Alzheimer’s inspectable.

Proteus Arc asks whether changing relationships across EEG channels can help researchers study Alzheimer’s as a dynamic system—while keeping source, time, uncertainty, and missing evidence attached.

SOURCE	EEG over time	Preserve channel identity, event timing, quality flags, and visible gaps.
RELATION	Changing dependencies	Explore whether relationships carry information that isolated averages lose.
TOPOLOGY	Groups beyond pairs	Represent proposed higher-order structure without hiding it inside a score.
CONTEXT	AI questionnaire	Add governed lived context while preserving self-report limits and human review.
BOUNDARY	Uncertainty in frame	Show provenance, absent inputs, model limits, and what remains unvalidated.

Fundamental commitment: a brain-health hypothesis should be legible before it becomes influential.

WIDEN THE RESEARCH DOOR

Specialist scarcity should not decide who gets seen.

01

More accessible research inputs

EEG is comparatively portable, repeatable, and time-sensitive. A clinician-governed questionnaire could add structured context between visits. Neither replaces biomarkers, imaging, neurological examination, or clinical judgment.

02

Knowledge as infrastructure

Methods, limits, and receipts should be understandable to more scientists, clinicians, families, and builders. Shared questions can strengthen studies and inspire future cures.

03

Evidence people can challenge

Every interpretation should retain its inputs, proposed operation, uncertainty, and missing evidence. “I don’t know” belongs in the interface.

Boundary: This vision does not promise a cure, diagnosis, screening service, research enrollment, or clinical access today.

EEG + AI QUESTIONNAIRE EVIDENCE LEDGER

Potential benefit, paired with its failure mode.

INPUT	POTENTIAL BENEFIT	PROBLEM TO SOLVE	PROPOSED RESPONSE
EEG temporal dynamics	Millisecond-scale electrical change	Limited spatial specificity and volume conduction	Keep channel and topology context visible; do not infer anatomy
Repeat EEG sessions	Portable longitudinal measurement	Setup variation, electrode drift, instability	Attach acquisition provenance, baselines, and uncertainty
EEG signal quality	Rhythmic and event-level visibility	Motion, muscle, eye, and environmental artifact	Expose quality flags and missingness; never silently repair
AI questionnaire	Structured cognitive and functional context	Recall, self-report, language, and access bias	Display source and uncertainty; preserve review and opt-out
EEG + questionnaire	Signal plus lived experience	Missing or misaligned inputs create false confidence	Separate provenance receipts; make absent inputs explicit

“AI questionnaire” means a proposed, clinician-governed research instrument—not an autonomous diagnostic chatbot.

TRUST BEGINS WITH WHAT IS WITHHELD

Nothing becomes trustworthy by disappearing.

WHAT IS LIVE

A deterministic public prospectus, inspectable interface simulation, and downloadable evidence record.

WHAT IS NOT LIVE

EEG ingestion, questionnaire delivery, artifact processing, model training, inference, calibration, validation, diagnosis, or care.

HUMAN ROLE

Question assumptions, inspect provenance, review evidence, and decide whether a research claim deserves further study.

PRIVACY

Do not send personal medical data or EEG files by email. The contact inbox is correspondence—not clinical intake.

Make the method more rigorous.

Research collaboration, scientific review, access, public knowledge, product, and responsible AI.
